↳ Articulation Point.

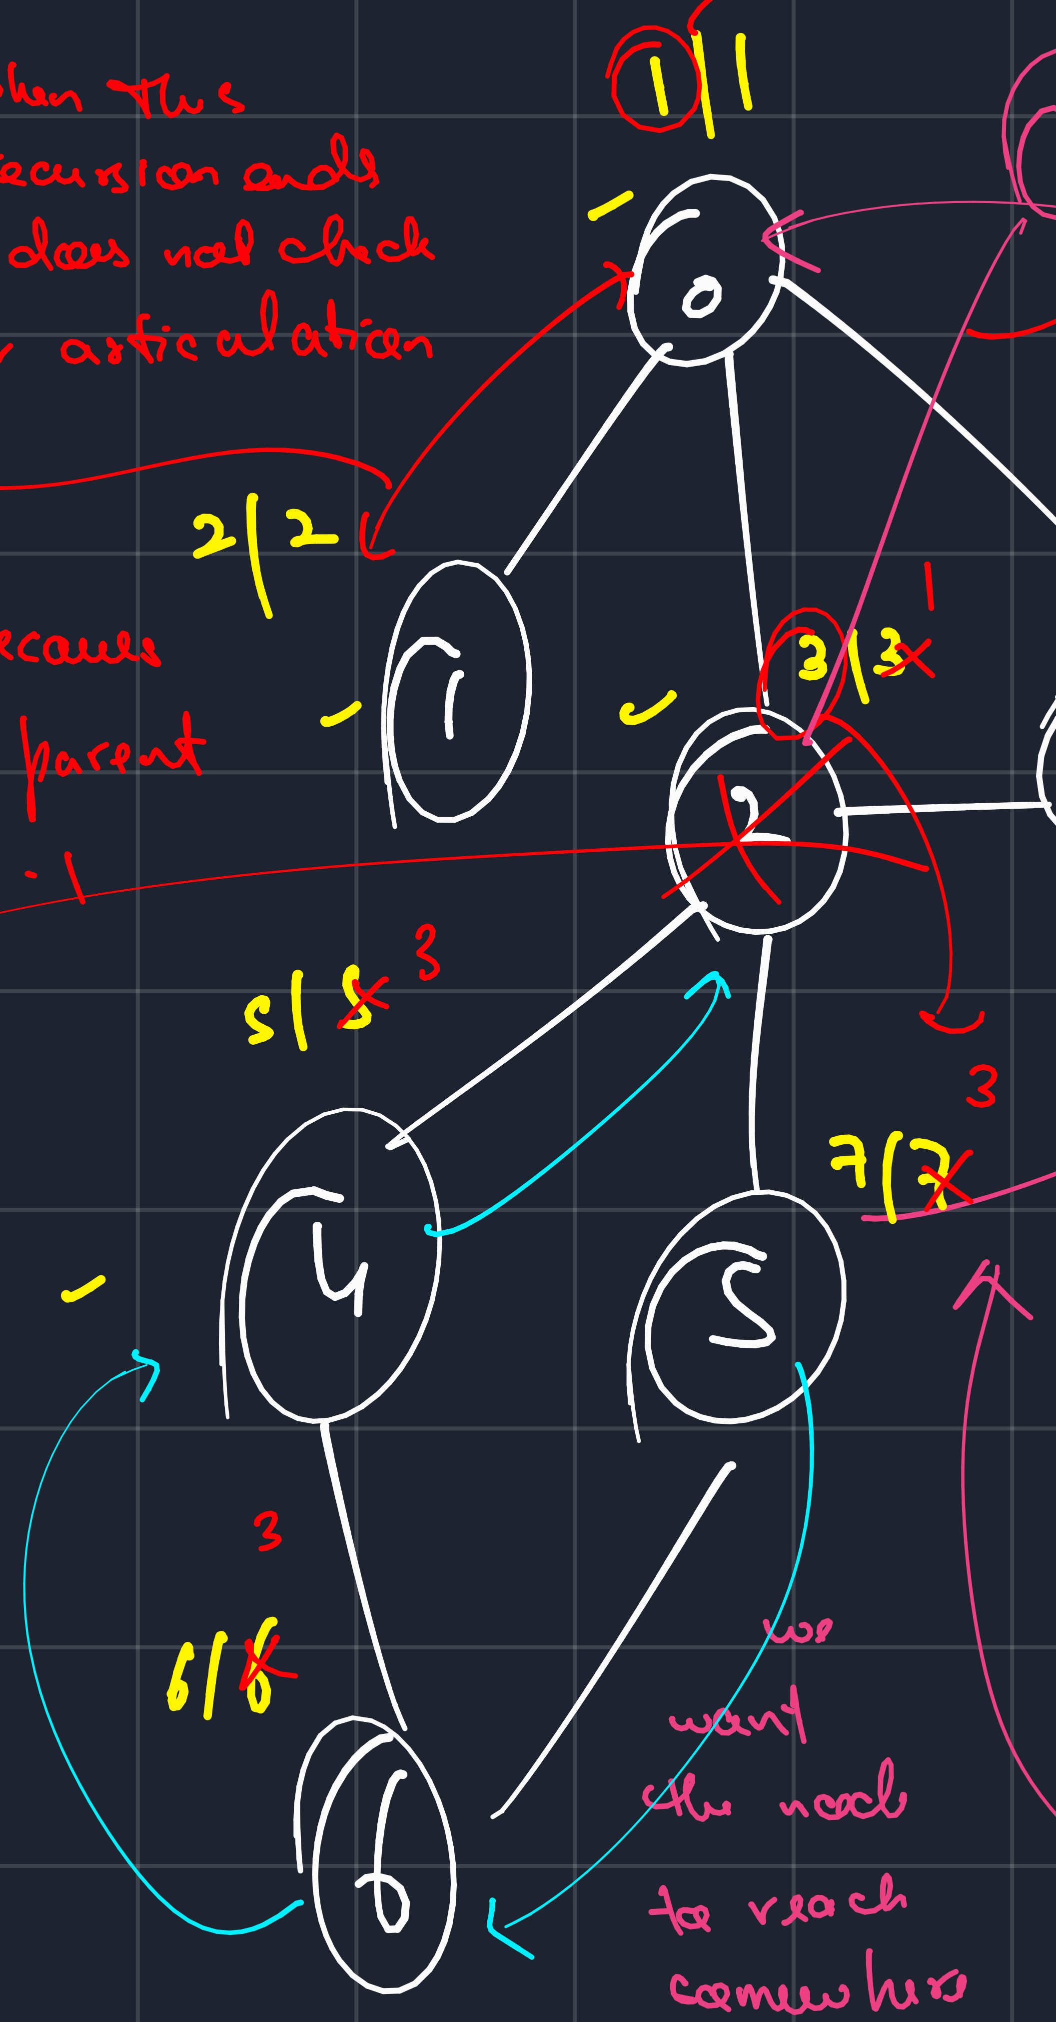
↳ nodes on whose removal the graph breaks into multiple components.

↳ we use the tin [ ] same as of bridges in graph

↳ low [ ]

↳ min of all adjacent nodes apart from parent & visited nodes.

tin | low



this component will also find 2 as the articulation point

when this recursion ends 0 does not check for articulation

because 0's parent is -1

if it is a visited node, do not take their low, take their tin, because suppose 2 was 3|1, 7 took 1 and became 7|1, but if we remove 2 → there is no way for 5 to reach 1.

we want the node to reach somewhere before the parent, because we removed "parent"

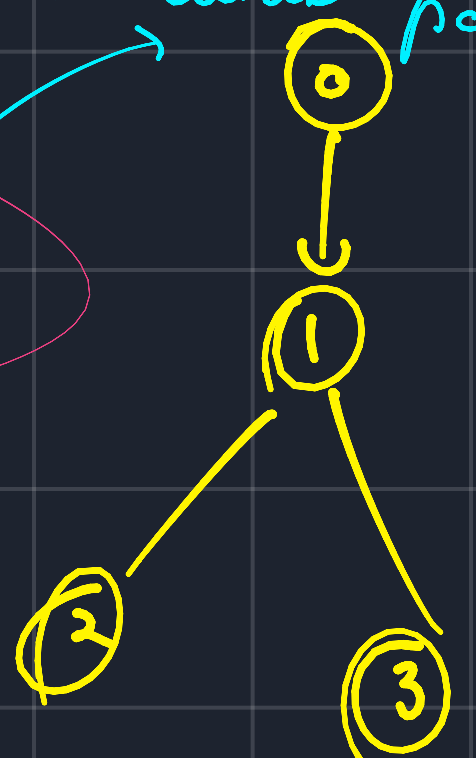
↳ the value of neighbor can never be equal to the parent

articulation → {0, 2} points

updated condition

↳ if (low [it] >= tin [node] && parent != -1)

starting point can never be articulation point



DFS(2) 3|3

DFS(4) 5|3

→ 2's time of entry is 3

→ low of 4 is 3

↳ So it can reach 3 but can never reach before it. Bridge
